

Take home: Cash Safe LTV Health

A core part of how [ether.fi](#) cash works is that users can borrow against the assets on their vault as they spend using their card

- The amount they can borrow is based on the sum of the weighting of each asset value and it's LTV
- If their borrow amount exceeds the liquidation threshold of their total account balance, then their assets can be liquidated to repay the borrowed amount

Current UI for a user that has a borrow and assets in borrow mode

The total of user safe balances and borrow amounts can be seen on our public [dune dashboard](#)

TASK

Build out a monitoring system that lets ether.fi monitor the health of all user safes

- You are free to use AI tools, be prepared to speak about your design choices
- This task is time boxed to 48 hours
- Once complete please share your code with us in a github repo
 - This should include a readme, and a quick start guide
- Once code is shared we will schedule a follow up call to do some pair programming

Technical details and getting started

The basic flow for a borrow is pretty simple

- `spend()` is called against the user safe
- if the safe is in borrow mode, then USDC is borrowed from the debt manager, and the debt is recorded in then debt manager

- there is also a [lens contract](#) that can be used to fetch read data on a safe
- public contract repo: <https://github.com/etherfi-protocol/cash-v3/tree/master>
